

NextGenTradingBot

Complete Configuration Reference — config6.json

All settings explained with current values and guidance

1. Global Settings

paper

Current value: false

Determines whether the bot trades with real money or in a simulated paper trading environment.

Value	Meaning
true	Paper trading — simulated orders, no real money at risk. Use for testing.
false	Live trading — real orders placed with real money. Currently active.

WARNING: You are currently in LIVE mode (false). All trades use real funds.

symbols

Current value: ["BBAI", "SOUN", "KULR", "GFAI", "STRC"]

The list of stock ticker symbols the bot monitors and trades. Each symbol runs its own independent trading loop simultaneously.

To add a symbol: Add the ticker to the array and add a matching entry in per_symbol_settings.

To remove a symbol: Remove it from both the array and per_symbol_settings.

interval_seconds

Current value: 1800 (30 minutes)

How often the bot wakes up, checks indicators, and decides whether to trade — for each symbol.

Value	Frequency	Best For
300	Every 5 minutes	Aggressive, fast-moving stocks
900	Every 15 minutes	Active but controlled trading
1800 (current)	Every 30 minutes	Balanced — not too frequent
3600	Every 60 minutes	Conservative, low-frequency trading

Lower values = more API calls and more trade opportunities. Higher values = calmer, fewer signals checked.

sma_period

Current value: 20

The number of hourly candles used to calculate the Simple Moving Average (SMA). The SMA is displayed in logs for context but does not directly trigger trades — RSI drives entries.

20 (current) = 20-hour SMA. Standard short-term trend indicator.

50 = Longer-term trend, smoother but slower to react.

10 = Very short-term, reacts quickly but noisier.

risk_pct

Current value: 0.01 (1%)

Controls how much of your total account equity is risked on a single trade. The bot uses this to calculate how many shares to buy.

Formula used internally:

```
risk_amount    = equity x risk_pct
stop_distance  = price x stop_loss_pct
qty            = risk_amount / stop_distance
```

Real example with current account (~\$176 equity, KULR at \$2.89):

```
risk_amount    = $176 x 0.01 = $1.76
stop_distance  = $2.89 x 0.02 = $0.058
qty            = $1.76 / $0.058 = ~30 shares (then capped by max_exposure_pct)
```

Value	Risk Per Trade	Effect
0.005	0.5%	Very conservative — fewer shares
0.01 (current)	1%	Balanced
0.02	2%	More shares per trade
0.05	5%	Large positions — high risk

Simple rule: smaller = less to lose but less to gain. At \$176 equity, 0.01 risks only ~\$1.76 per trade — hence the small share quantities you see.

max_holding_period

Current value: 5 (days)

The maximum number of calendar days the bot will hold an open position. If a position is still open after this many days, the bot forces a close regardless of profit or loss.

Value	Meaning
1	Day trading style — closes everything by end of day
5 (current)	Hold up to 5 days — swing trade style
10	Longer swing trades
30	Near position trading

Acts as a safety net to prevent the bot from being stuck in a losing position indefinitely.

max_exposure_pct

Current value: 0.1 (10%)

The maximum percentage of your total equity that can be allocated to a single position. This acts as a hard cap on position size regardless of what risk_pct calculates.

Example: With \$176 equity at 0.10, no single position can exceed \$17.60 in value.

Value	Max Per Position	Style
0.05	5% of equity	Very conservative
0.10 (current)	10% of equity	Balanced
0.15	15% of equity	More concentrated bets
0.25	25% of equity	High conviction trades

enable_trailing

Current value: false

Switches the bot between two completely different exit strategies — fixed bracket orders or trailing stops.

false (current) — Bracket Orders

Exit prices are fixed at the moment of entry and never change.

```
Buy KULR at $2.89
  Stop Loss   → fixed at $2.83  (2% below entry)
  Take Profit → fixed at $3.03  (5% above entry)
```

true — Trailing Stop

The stop loss follows the price upward automatically, locking in gains as the stock rises. No fixed take profit.

```
Buy KULR at $2.89 → Trailing stop at $2.83
Price rises to $3.10 → Stop moves up to $3.04
Price rises to $3.50 → Stop moves up to $3.43
Price drops to $3.43 → SOLD, gain locked in
```

	false — Bracket	true — Trailing
Take Profit	Fixed target price	No fixed target
Stop Loss	Fixed price	Moves up with price
Best for	Range-bound stocks	Trending/momentum stocks
Risk	Misses big runs	Can give back more gains

Simple rule: if you think the stock will hit a target and reverse, use false. If you think it could keep running, use true.

metrics_interval_seconds

Current value: 1800 (30 minutes)

How often the bot calculates and reports performance metrics (win rate, P&L ratio, Sharpe ratio) to logs and Discord.

1800 (current) = Reports every 30 minutes

3600 = Reports every hour

900 = Reports every 15 minutes (more frequent updates)

Metrics are only meaningful once trades have been filled. Early in a session you will see 'No filled trades' — this is normal.

2. Per-Symbol Settings (per_symbol_settings)

Each symbol has its own independent set of trading parameters. This allows the bot to behave differently for each stock based on its volatility and characteristics.

Current Configuration Summary

Symbol	RSI Buy	RSI Sell	Stop Loss	Take Profit	RSI Period
BBAI	28	72	1.5%	4%	14
SOUN	25	75	2.0%	6%	14
KULR	30	70	2.0%	5%	14
GFAI	27	70	1.8%	4.5%	14
STRC	27	70	1.8%	4.5%	14

rsi_buy_threshold

How oversold the stock must be (RSI value) before the bot enters a long (buy) position. RSI ranges from 0 to 100 — lower means more oversold.

Value	Behaviour
20 or lower	Very selective — only buys on extreme dips
25-28 (SOUN/BBAI)	Moderately selective — requires meaningful dip
30 (KULR)	Standard — classic oversold threshold
35 or higher	Aggressive — buys more frequently, earlier in dips

SOUN has the tightest buy threshold (25) — the bot waits for a bigger dip before entering. KULR is most relaxed at 30.

rsi_sell_threshold

How overbought the stock must be (RSI value) before the bot exits a long position or enters a short. Higher means more overbought.

Value	Behaviour
70 (KULR/GFAI/STRC)	Standard overbought threshold
72 (BBAI)	Slightly more selective — waits a bit longer
75 (SOUN)	Most selective — requires stronger overbought signal
80 or higher	Very selective — only acts on extreme overbought

stop_loss_pct

How far the price can fall from entry before the bot cuts the position to limit losses.

Symbol	Value	Meaning
BBAI	0.015	Cuts at 1.5% loss — tight protection
SOUN	0.020	Cuts at 2.0% loss — standard
KULR	0.020	Cuts at 2.0% loss — standard
GFAI	0.018	Cuts at 1.8% loss — slightly tight
STRC	0.018	Cuts at 1.8% loss — slightly tight

Tighter stop loss = more protection but higher chance of being stopped out by normal price noise. Looser = more room to breathe but bigger loss if wrong.

take_profit_pct

How much the price must rise from entry before the bot closes the position and takes the gain.

Symbol	Value	Meaning
BBAI	0.04	Takes profit at 4% gain
SOUN	0.06	Takes profit at 6% gain — lets it run more
KULR	0.05	Takes profit at 5% gain — standard
GFAI	0.045	Takes profit at 4.5% gain
STRC	0.045	Takes profit at 4.5% gain

SOUN has the highest take profit (6%) — the bot waits for a bigger gain before exiting. BBAI exits quickest at 4%.

rsi_period

Current value (all symbols): 14

The number of candles used to calculate RSI. All symbols currently use the standard 14-period RSI.

Value	Effect
7	Fast RSI — reacts quickly, more signals, more noise
14 (current all)	Standard — industry default, balanced sensitivity
21	Slow RSI — fewer but stronger signals

3. Risk / Reward Ratios by Symbol

Based on current stop_loss_pct and take_profit_pct settings, here is how much the bot stands to gain vs lose on each symbol per trade.

Symbol	Stop Loss	Take Profit	R:R Ratio	Meaning
BBAI	1.5%	4.0%	1 : 2.67	Win \$2.67 for every \$1 risked
SOUN	2.0%	6.0%	1 : 3.00	Win \$3.00 for every \$1 risked
KULR	2.0%	5.0%	1 : 2.50	Win \$2.50 for every \$1 risked
GFAI	1.8%	4.5%	1 : 2.50	Win \$2.50 for every \$1 risked
STRC	1.8%	4.5%	1 : 2.50	Win \$2.50 for every \$1 risked

All symbols have favourable R:R ratios above 2.5 — meaning the bot only needs to win roughly 1 in 3 trades to be profitable overall.
